have. Phylogeny and diversity of *Tetraspora* yeasts in *Arabidopsis thaliana* roots. The phylum Tetrastromycotina includes the genera *Tetraspora*, *Verticillium*, and *Fusarium*, among others. There are many ascomycetous species in the phylum, most of them belonging to the families Diaporthaceae and Myriangiaceae, but the phylogenetic relationship between these taxa remains largely unresolved. The *Arabidopsis thaliana*-*Tetraspora* endophytic complex was investigated. Thirty-seven isolates were obtained from 16 accessions belonging to the *A. thaliana* natural accession population. Strains were characterised by partial sequencing of the large subunit rRNA gene and the internal transcribed spacer region (ITS) and further identified by analysis of the small subunit rRNA (SSU rRNA). Phylogenetic analysis showed that the 37 isolates belong to two different clades: clade I includes isolates from biotypes Sp and Uns; and clade II includes isolates from biotypes U and W. The two clades are distantly related and the separation time seems to be a recent event. Strains of clade II may represent a new *Tetraspora* species, while strains of clade I appear to be a subclade of the *Tetraspora reesei*-clade, including the type strain. *A. thaliana*-*Tetraspora* isolates harboured a diverse range of fungi and bacteria including several *Fusarium* species, one of them belonging to the newly described taxon *Fusarium novae-zelandiae*. Other bacteria, most likely endophytic bacteria, were also isolated from the root surface and endosphere.

What's New In WideAwake?

In a random state where 1's or 0's is taken with a probability of $\sim 1/2$ the output of a periodic xor cot algorithm is either a sequence of zeroes (00100..01111) or ones (10111..11100). This is a pattern that is represented by a binary tree. The first node is either a leaf with a 0 or 1, or the left or right children are itself two more levels of the tree. The third level of the tree is represented by loghack or sneak steps, with a probability of $\sim 1/3$ a zeroes is replaced by ones, or the reverse. The fourth level is a copy of the last (and therefore the top) level of the tree, with a probability of $\sim 1/3$ equal to the probabilities of the loghack or sneak step. The middle of the tree is always filled with 0s.
