When preparing your images for Photoshop, you have to know the basic rules of the game. First, always save your files in RAW (or DNG) format, whether you work in Photoshop or you edit your photos with other tools. (If you work in a RAW editor, be sure to check out Chapter 10 for detailed information on that program.) RAW files have the best color and image quality because their data is unprocessed, so you can correct any errors after you shoot. Second, select a file type that's the most compatible with Photoshop. If you photograph a lot of people, or you often create highly detailed images, you can take advantage of .psd files. You also have to consider your file size: If you're planning to post images online, limit your file size to a maximum of 5 megapixels. Keep in mind that you can drop or drag images into Photoshop (as well as into other programs) — they won't take on any extra size. And be sure to work with a file that's not too small, either, because small files tend to degrade the quality of your image significantly. Photoshop not only supports GIF, JPEG, and TIFF formats, it also supports Photoshop files (PSD) and .BMP images. You can use these file types with Photoshop if you choose.

Examining Photoshop's Preferences

When you launch Photoshop, you find a number of options that let you configure Photoshop for your current needs. You can adjust your resolution settings and choose what images you want to import. To get started, here's a quick rundown of some of the options that you can control in Photoshop:

Resolution: Most people have a preference for a particular number of pixels per inch (ppi). For web images, the recommended number of pixels is 72 ppi. For print images, the recommended number of pixels is 300 dpi.

Scale: Photoshop has a variety of scaling options, ranging from 1:1 or 100 percent to 200 percent. Auto-scale is the best option for most people.

Color Mode: You may want to use a color mode that works best with your particular type of photo — such as black-and-white, grayscale, or RGB.

Image Size: You can choose

Participation of recombinant tissue plasminogen activator (rt-PA) in the fibrinolytic system of humans. A focus on rt-PA. In experimental animal models, the amount of thrombolytic activity derived from recombinant tissue plasminogen activator (rt-PA) may be sufficient to induce fibrin lysis. Recent studies have suggested that rt-PA is at least as active as endogenous tissue plasminogen activator (t-PA) in the lysis of human fibrin, but the low rt-PA concentration required and the potential for antigenic reactions suggest that its clinical usefulness remains to be evaluated. We determined the fibrinolytic, thrombin-inducible fibrinolytic, and immunoreactive fibrinolytic activity of the commercially available preparation in the presence of plasminogen activators with which it is administered together in intravenous infusions. At a dose of 90 micrograms/kg, rt-PA accounted for 50% of the total fibrinolytic activity. In plasminogen-depleted plasma, rt-PA had a thrombin-inducible component of 15% of total fibrinolytic activity. The thrombin-inducible fibrinolytic activity could be removed from both preparations by immunoadsorption, although activity was retained in one preparation. The thrombin-inducible fibrinolytic activity of rt-PA was comparable to that of t-PA. We also detected immunoreactive fibrinolytic activity in platelet-poor plasma, with a mean concentration of 41 fibrinolytic units/mL. Because rt-PA is a 50% thrombin-inducible fibrinolytic activity with residual immunoreactivity, its clinical usefulness should be evaluated in clinical trials.

Q: Confusion regarding numpy's `clip_nan` and `clip` I have been attempting to use numpy.clip to clip or clip-around isolated nan values in a numpy array. The following code illustrates the situation I have been running into: `import numpy as np a = np.array([10,10.0, np.nan]) x = np.array([1,10.0, np.nan]) y = np.array([1, 10, np.nan]) print(a) # [10. 10. nan] print(a.clip_nan(0)) # [10. 10. nan] print(a.clip(0,1)) # [10. 10. nan] print(y[1]) # nan print(x[1]) # 10.0` As you can see, the nan is not clipped when clip_nan is used. A: numpy.clip returns a scalar with the limits as described in the documentation. `>>> print(np.clip(a, 0, 1)) nan` And this is a valid argument with np.clip. If you need to clip a NumPy array, then you have to do it yourself. `>>> a = np.array([10,10.0, np.nan]) >>> a[1:] = np.clip(a[1:], 0, 1) >>> a array([10. , 10. , 10.])` If you don't want a scalar, you have to use np.clip_to instead (for numpy >= 1.12.0). `>>> a = np.array([10,10.0, np.nan]) >>> a[1:] = np.clip_to(a[1:], 0, 1) >>> a array([10. , 10. , 10.])`
